

Results

The present study was conducted in the Department of Microbiology, Assam University, Silchar, Assam, India. The duration of study was May 2013 to April 2015. The bacterial strains were collected from Silchar Medical College and Hospital, Silchar, Assam and different community health centres on Silchar town. This tertiary referral hospital serves around 38,26,110 numbers of populations of Assam and neighbouring states like North Tripura, Mizoram, Meghalaya and Manipur. Environmental samples were collected from different sites of five different rivers of southern Assam, water bodies near waste disposal site and food samples were collected from food vendor shops of Silchar town.

A total of 967 consecutive non-duplicate different clinical specimens have been studied during the period of May 2013 to April 2015 and a total of 130 consecutive non-duplicate different environmental samples were studied for the period of September 2014 to August 2015.

4.1 Isolation and identification of isolates from clinical specimens and environmental samples:

Clinical specimens were streaked on Mac-conkey agar, Blood agar and CLED agar (for urine specimen), whereas the environmental samples were streaked on Mac-conkey agar and their microscopical observation by Gram staining, motility and cultural characteristics were observed as mentioned (Table 16). All the enterobacterial isolates were rod shaped and stained pink in colour. They were further investigated with different biochemical reactions and interpreted accordingly. Lactose fermenting pink colonies were observed for *Escherichia coli* and *Klebsiella* spp.(Figure 9a,9b,9c).

Table 16: Cultural characteristics:

Organisms	Colony morphology on MacConkey agar, Blood agar and CLED agar	Motility
<i>Escherichia coli</i>	Shiny, pink coloured lactose fermenting colonies on Macconkey agar and beta haemolytic colonies on blood agar.	Motile
<i>Klebsiella</i> spp.	Mucoid, pink coloured lactose fermenting colony and non haemolytic mucoid colony on blood agar.	Non-Motile
<i>Proteus</i> spp.	Colourless, non-lactose fermenting on CLED agar.	Motile

4.1.1 Identification of isolates by biochemical test:

As per interpretation of the results of biochemical reaction, a total number of 212 isolates were found belonging to the member of Enterobacteriaceae family. Among them, predominant type was *Escherichia coli* (n=139), followed by *Klebsiella pneumoniae* (n=53), *Klebsiella oxytoca* (n=7) and *Proteus* spp. (n=12) (Table 17).

4.2 Samples:

4.2.1 Clinical isolates:

A total of 864 bacterial isolates were obtained of which 212 were identified as members of Enterobacteriaceae comprising 80 isolates from Silchar Medical College and Hospital and 132 from different community health centres (Table 18).

Table 18: Different isolates obtained from clinical sample in the study.

Name of Organisms	Hospital	Community	Total
<i>Escherichia coli</i>	42/80 (Urine=38, stool=3, Pus=1)	97/132 (Urine=94, stool=3)	139
<i>Klebsiella pneumoniae</i>	30/80 (Blood=6, Throat swab=1, sputum=7, Tracheal aspirate=1, Pus=9, urine=6)	23/132 (sputum=10, pus=5, throat swab=8)	53

Fig.9b Colony morphology of *Klebsiella* spp.on Macconkey agar

Fig.9c Colony morphology of *Proteus* spp.on Macconkey agar

4.2.2 Environmental isolates:

A total of 153 bacterial isolates were isolated of which 68 (44.44%) were identified as Enterobacteriaceae (Table 19).

Table 19: Different isolates obtained from environmental samples in the study

Name of organisms	Water samples from river	Water samples near waste disposal sites	Food samples from vendor shops	Total

Total	26	35	7	68

4.3 Phenotypic screening of quinolone resistance:

When screened for quinolone resistance nalidixic acid showed highest resistance (88.68%) followed by lomefloxacin (87.74%), ciprofloxacin (76.42%) and sparfloxacin (74.06 %) (Table 18; Figure 9 and 10).

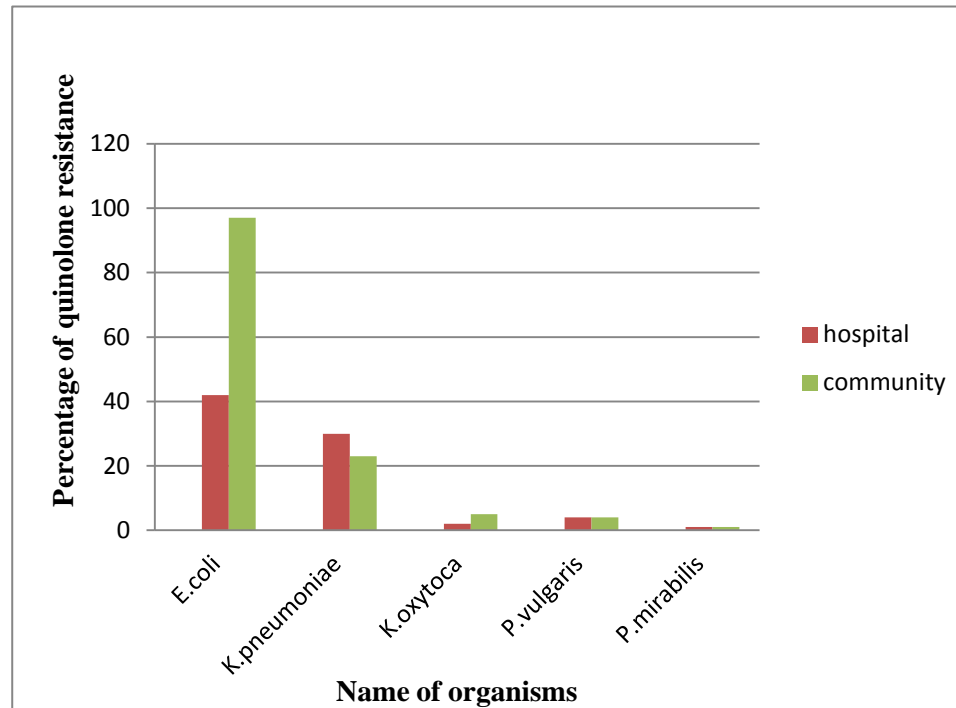

Figure 11: Proportion of quinolone resistant enterobacterial hospital (n=79) and community (n=130) isolates at species level

4.3.1: Resistance tree based on quinolone antibiotic resistance pattern

Based on the quinolone resistance profile of the clinical isolates a total of 17 different resistance pattern were observed; among which 12 patterns were obtained for *E. coli*, 7 for *Klebsiella pneumoniae*, 4 for *Klebsiella oxytoca*, 3 for *Proteus vulgaris* and 2 for *Proteus mirabilis*. Pattern1 was observed to be the most prevalent in all organisms except *Proteus mirabilis*. In *Proteus mirabilis* pattern 3 and pattern 6 were observed (Table 21).

4.4 Minimum inhibitory concentration

4.4.1 Minimum inhibitory concentration against quinolones in clinical isolates.

Among all the fluoroquinolone resistant clinical isolates, highest susceptibility was observed against levofloxacin 36.36% (n=76) and gatifloxacin 35.89% (n=75) followed by ofloxacin 33.49% (n=70); norfloxacin 32.54% (n=68); ciprofloxacin 22.01% (n=46) and rest of the isolates were above the MIC break point (Table 23-27 and Figure 12).

4.5 Genotypic characterization of quinolone resistant isolates:

4.5.1 Genotypic characterization of quinolone resistant clinical isolates:

Multiplex PCR results showed presence of different quinolone resistance determinants, among them *aac(6')-lb cr* (n= 23) was most common followed by *qnrD* (n=18), *qnrA* (n=7), *qnrS* (n= 4), *qnrB* (n= 2) (Figure 13). A total of 54 (25.83%) isolates were harbouring single *qnr* gene (Table 32), while in 18 (8.61%) isolates multiple *qnr* genes were found (Table 33). There were 137 isolates which did not show any amplification with target primers.

4.5.2 Genotypic characterization of quinolone resistant environmental isolates:

Multiplex PCR results showed presence of different quinolone resistance determinants, among them *aac(6')-lb cr* (n= 25) was most common, followed by *qnrD* (n=7), *qnrA* (n=5) and *qnrS* (n= 2) (Table 32; Figure 14).

4.7 Transferability of *qnr* genes and *aac(6')Ib-cr* genes:**

4.7.1 PCR detection of *qnr* genes and *aac(6')Ib-cr* genes in transformants:**

A total of 98 clinical isolates and 36 environmental isolates were subjected to transformation assay, of which transformation was successful with 82 (83.67%) clinical and 36 (100%) environmental isolates (Figure20). PCR was performed for all the transformants and results indicative that all the *qnr* and *aac(6')**Ib-cr* genes could be transformed successfully to the recipient strain in case of clinical isolates while in case of environmental isolates only *qnrS* and *aac(6')* *Ib-cr* could be successfully transformed.

4.7.2 Selection specificity of *qnr* genes:

The transformants carrying the PMQR determinants showed biasness during selection towards the quinolone antibiotics. Transformants which carried the *qnrA* determinants were selected from the media containing norfloxacin, ciprofloxacin and levofloxacin; *qnrB* positive transformants were selected from the media containing norfloxacin, ciprofloxacin; *qnrD* positive transformants were selected from the media containing norfloxacin, ofloxacin; *qnrS* positive transformants were selected from the media containing levofloxacin and the transformants which carried the *aac(6')**Ib-cr* genes were selected from the media containing norfloxacin and ciprofloxacin (Table 35).

4.7.3 MIC of transformants:

High MIC₅₀ and MIC₉₀ was observed against all tested fluoroquinolones in transformants of members of Enterobacterial isolates harbouring single and multiple *qnr* genes (Table 36-40). MIC₅₀ and MIC₉₀ of the transformants against norfloxacin and ciprofloxacin ranged between (2-4 µg/ml), against ofloxacin and gatifloxacin ranged between (1-4 µg/ml), whereas for levofloxacin the range is 0.5-2 µg/ml.

4.8 Analysis of plasmids:

Plasmid was analysed for the transformants harboring *qnr* gene of each type and the observation was as follows: A 25kb plasmid was found in the isolates carrying *qnrA*, 15kb and 20kb was found carrying *qnrD*, 20kb was found carrying *qnrB*, 25kb was found carrying *qnrS* and 18 kb and 20kb plasmid was found in the isolates carrying *aac(6')Ib-cr* genes (Figure 21).

4.9 Plasmid Incompatibility typing:

Plasmid incompatibility group typing in transformants suggested that *qnrA* was located within P, HI1, B/o, T, F_{rep}B, K/B and I1 Inc type; *qnrB* was located within F_{rep}B, K and I1 Inc type; *qnrD* was located within F_{rep}B, FIB, K/B, P Inc type; *qnrS* was located within F_{rep}B and K/B Inc type; *aac(6')Ib-cr* was located within HI2, FII, K/B, P, F_{rep}B, FIB Inc type (Figure22;Table 41-45). Isolates harbouring multiple *qnr* genes were originated through diverse Inc group types viz: HI1, I1, W, Y, P, F_{rep}B, K, B/o (Table 44).FIB, F_{rep}B, K/B and HI2 were the most predominant

Inc type present among the isolates. F_{repB} Inc type was found common among *K.pneumoniae*.

4.10 Analysis of conjugative transferability of plasmid

Conjugation experiment was performed with 82 isolates and it was found that 76 (92.68%) isolates were conjugatively transferable (Figure23). Resistance pattern of these transconjugant against quinolone antibiotics were confirmed by disc diffusion test (Figure 24 A and B).

4.10.1 PCR detection of *qnr* among transconjugants:

PCR results were indicative that *qnr* genes were present in all the transconjugant plasmids.

4.10.2 MIC of transconjugants:

High MIC₅₀ and MIC₉₀ were observed in all transconjugants against all tested quinolones antibiotics (Table47-51). MIC₅₀ and MIC₉₀ for all the transconjugants against norfloxacin, ciprofloxacin and ofloxacin ranged between 1-4 µg/ml whereas against gatifloxacin and levofloxacin MIC₅₀ and MIC₉₀ ranged between 0.5-2 µg/ml (Figure 24C and D).

4.11 DNA fingerprinting of quinolone resistant isolates by ERIC PCR

After performing ERIC PCR, 74 types of *Escherichia coli*, 21 types *Klebsiella pneumoniae*, 3 types of *Klebsiella oxytoca*, 3 types *Proteus vulgaris* and 2 types *Proteus mirabilis* were found in the study (Figure 25A,B,C).

4.12 Determination of genetic environment:

4.12.1 Detection of the location of *qnr* gene within integron region:

Sequencing of the amplified products revealed that *qnrD* and *aac(6')Ib-cr* were located within the variable region of class 1 integron whereas other quinolone determinants showed no association with the gene capture mechanism.

4.12.2 Association of *qnr* and *aac(6')Ib-cr* genes with mobile element:

Sequencing results showed that *qnrA* genes were linked with *tnISEcp1*; *tnIS26*; and *IS26* in the upstream region while in case of *aac(6')Ib-cr* the upstream region showed the presence of *tnIS26*. No association was observed in other quinolone resistance determinants associated with mobile genetic elements.

4.13 Study of mutation in the quinolone resistance determining region by denaturing gradient gel electrophoresis:

All the quinolone resistant isolates that were devoid of quinolone resistance determinants were subjected to PCR amplification using primers listed in table 17. All the isolates showed positive results for PCR amplification with the primers used (Figure 26). Altogether 96 isolates were studied for mutation in the quinolone resistance determining region (QRDR) by DGGE. Four band patterns were obtained for each gene when compared with the positive control (Figure 27).

4.13.1 Sequencing of *gyrA* and *parC* genes:

The amplified products were subjected to DGGE. Analysis of the gel revealed four types (A-D) of band patterns of each of *gyrA* and *parC* genes. In order to determine the contribution of mutation in QRDR region which attributes fluoroquinolone resistance, sequencing of *gyrA* and *parC* patterns were done. When the DNA sequence of the *gyrA* was compared with *gyrA* subunit of EC493/89, it revealed nucleotide differences at many positions (Figure 28a and 28b). Pattern A were found to have 9 point mutations (EGYMU1), Pattern B with 13 point mutations (EGYMU2), Pattern C with 11 point mutations (EGYMU3) and Pattern D was found to have 10 point mutations (EGYMU4). Two transition mutations were common in all the isolates. Three insertion mutations were found between 166th and 167th base by T (starting with position 1 at the A of the start codon of *gyrA*) of *gyrA* pattern EGYMU1. At 181th and 190th base, deletion of single nucleotide A was observed in all *gyrA* pattern (Figure 28a). Mutation in codons 83 and 87 in *gyrA* displayed the most common alteration in clinical isolates. Transition mutation at codon 83 was a C-T that resulted in the substitution of leucine for serine in pattern A, B and D but in pattern C (EGYMU3) transition mutation at codon 83 resulted in the substitution of glycine for serine. Another transition mutation was C-A at position 87, which resulted in an Asp87Leu and Asp87 Asn. Twenty one different types of mutation in *gyrA* were found amongst the isolates analysed. They were Trp56Met, Asn57Thr,

Asn57His, Trp59Met, Asn60Thr, Asn60Asp, Lys61Gly, Lys61Ser, Ala62Thr, Ala62Pro, Tyr63Ser, Tyr63Ile, Lys64Leu, Lys65Ile, Ser83Leu, Ser83Gly, Val85Ala, Asp87Asn, Asp87Leu, Arg91Tyr and Ser111Asn.

The isolates showing the four mutation pattern of *parC* were named as EPRMU1, EPRMU2, EPRMU3, EPRMU4. Pattern EPRMU1 were found to have 10 point mutations, of which 5 insertion mutation with T. Transition mutation of A-G at base 251st and transversion mutation of G-C at base 325th were found in EPRMU2. Two transversion mutations C-A and two transition mutation C-T were observed in EPRMU3 (Figure 28a and 28b). Two transversion mutation G-T and C-A were detected in EPRMU4. Codons 74,76, 77, 80, 82, 84, 89, 91, 105, 107 showed alterations in the QRDR of the *parC* gene. The replacements were Tyr74Leu, Pro76Phe, His77Arg, Ser80Ile, Ser80Arg, Cys82Leu, Glu84Gly, Glu84Lys, Met89Leu, Gln91His, Asn105Thr and Gly107Ala. Mutations outside the QRDR were also observed during the study. A deletion of G at 390th base and a transversion of G-T at 393rd base have resulted in the substitution of Glu130Asp and Leu131Phe respectively (Figure 29a and 29b)

4.14 Therapeutic option:

In case of antibiotics other than quinolone antibiotics for treatment options, susceptibility was high against polymyxinB 83.25% (n=174) followed by imipenem 73.68% (n=154) and cefotaxime 66.99% (n=140) (Table 52; Figure30).

Figure 30: Antibiotic susceptibility of quinolone resistant isolates

Table 52: Antibiogram profile of quinolone resistant isolates:

Types of isolates	<i>E. coli</i> n=139		<i>Klebsiella pneumoniae</i> n=53		<i>Klebsiella oxytoca</i> n=7		<i>Proteus vulgaris</i> n=8		<i>Proteus mirabilis</i> n=2	
	N	%	N	%	N	%	N	%	N	%
